What's WebRTC?

What's WebRTC?

A set of protocols that allows for secure, P2P, real-time audio video exchange between browsers.

WebRTC applications

- Google Meet
- Discord
- Microsoft Teams
- Slack

Non-WebRTC applications

- YouTube
- Twitch

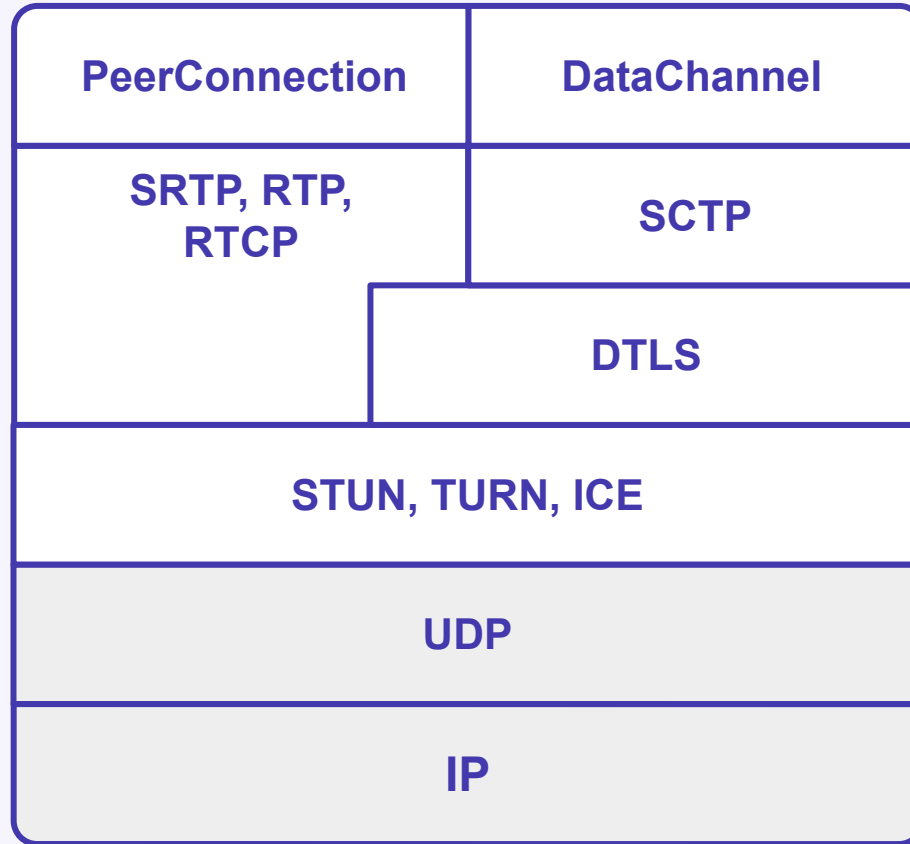

A set of protocols

- est. connection -> protocol A
- sending media -> protocol B
- encrypting media -> protocol C
- sending data -> protocol D
- encrypting data -> protocol E
- negotiating parameters -> protocol F

PeerConnection API

Real-time

- latency below 200ms
- data prioritization - audio is the most important, then video and its quality
- how to deal with poor networks - retransmissions, forward error correction, adaptive streaming, bandwidth estimation
- we have to be flexible and adapt to the changing environment

P2P

- we can directly connect two people that are in their private networks without forwarding traffic through a server
- one of the most important features of WebRTC

Secure

- data is always encrypted
- you cannot obtain access to audio and video devices from non-https websites (excluding localhost)
- video players are muted by default unless there is an interaction with the website

Implemented in web-browsers

											
	 Chrome	 Edge	 Firefox	 Opera	 Safari	 Chrome Android	 Firefox for Android	 Opera Android	 Safari on iOS	 Samsung Internet	 WebView Android
RTCPeerConnection	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓
	56	15	44	43	11	56	44	43	11	6.0	56

Ex. Create PeerConnection object in browser console

- <https://developer.mozilla.org/en-US/docs/Web/API/RTCPeerConnection/RTCPeerConnection>

A set of interfaces

- RTCPeerConnection - send/receive audio and video
- **getUserMedia** - obtain access to microphone and camera
- RTCDataChannel - send/receive arbitrary data

Ex. Obtain access to audio and video devices

- <https://github.com/elixir-webrtc/workshop/>
- ex1

When to use WebRTC?

- interactive communication
- video conferencing
- real-time audio/video AI processing (Speech-To-Text, Image recognition, conversations with bots)
- real-time broadcasting (Broadcaster, broadcast-box)
- telemedicine

WebRTC is standardized by W3C and IETF

W3C - responsible for API for web browsers. It's the same organization that stays behind e.g. CSS

- <https://www.w3.org/TR/webrtc/>
- <https://www.w3.org/TR/css-flexbox-1/>

IETF - responsible for specific protocols (ICE, RTP, SDP, etc.) described in RFC documents

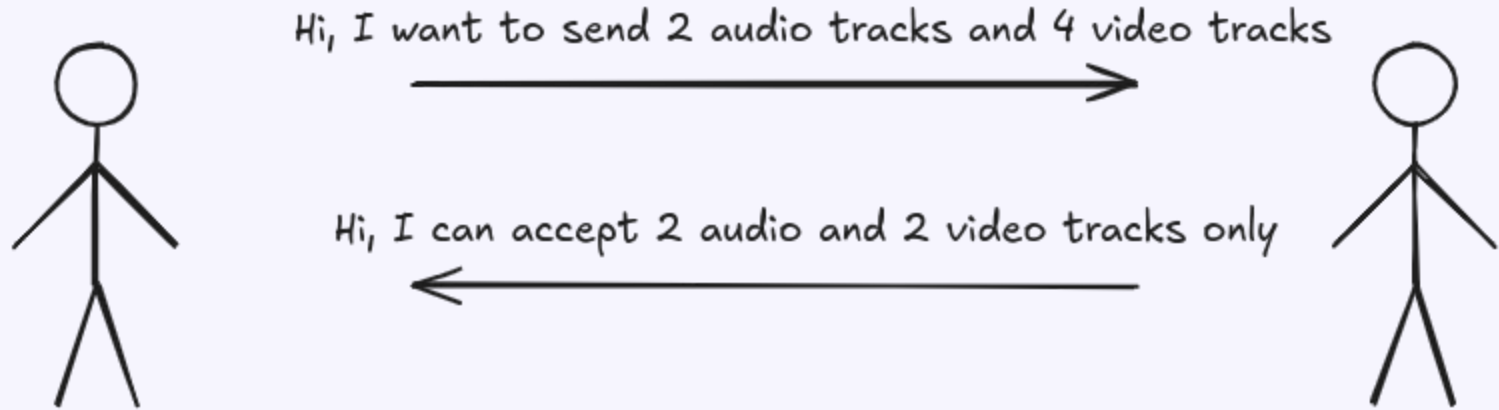

- <https://datatracker.ietf.org/doc/html/rfc8829>

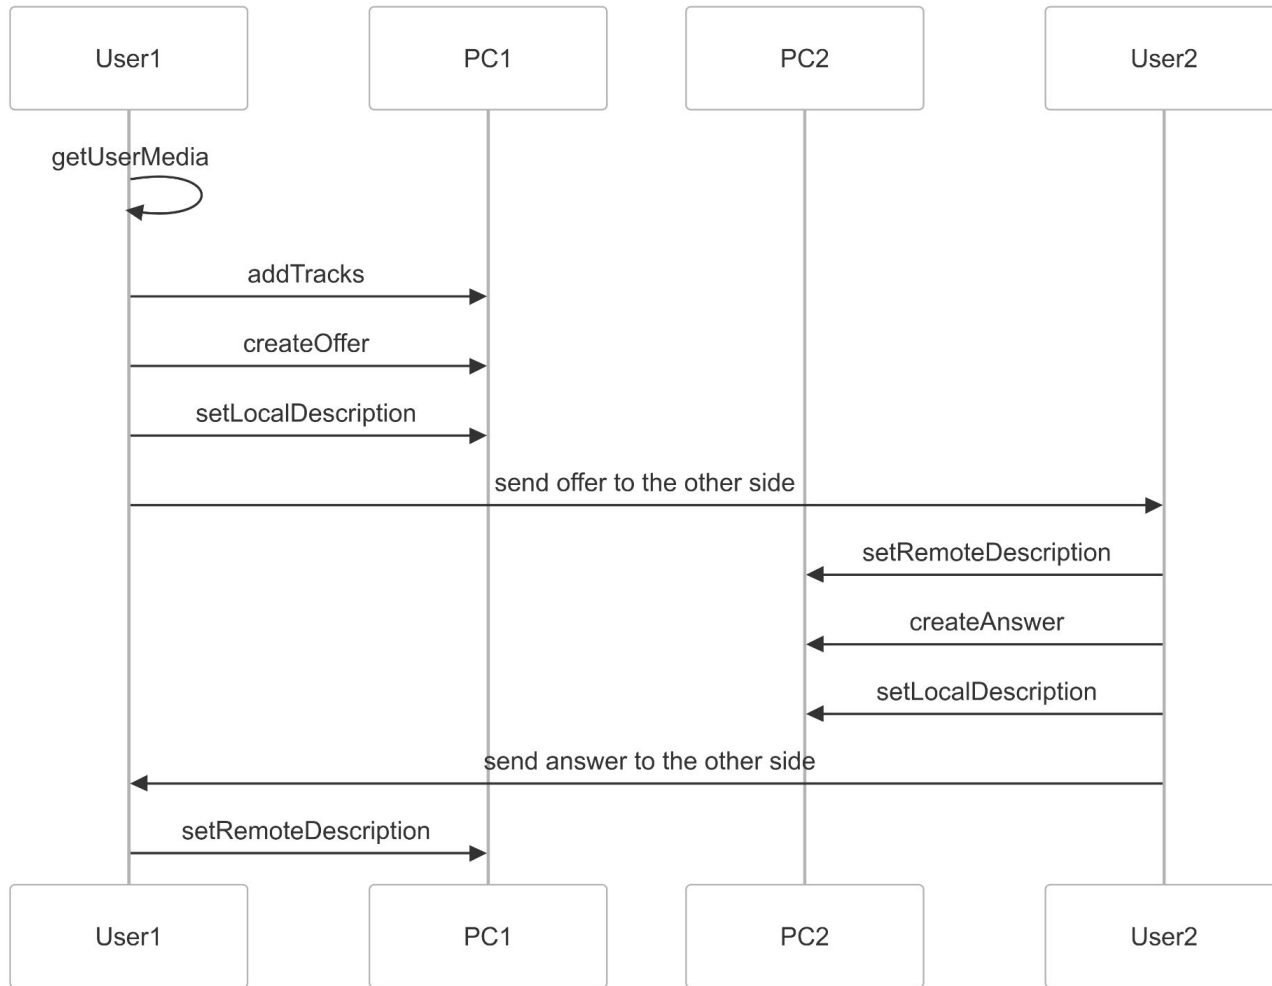

Documentation:

- <https://developer.mozilla.org/en-US/docs/Web/API/RTCPeerConnection>

Negotiating session parameters

Ex. Negotiate session parameters

- <https://github.com/elixir-webrtc/workshop/>
- ex2

Ex. Implement ontrack callback

- https://developer.mozilla.org/en-US/docs/Web/API/RTCPeerConnection/track_event
- pin received MediaStream to the video player
- Hint: use **event.streams[0];**

WebRTC monitoring and debugging

Ex. Use <chrome://webrtc-internals> to find an answer to the following questions:

- What is the state of (Peer)Connection?
- What is the state of ICEConnection?

What is ICE?

How does the Internet work?

ICE

A technique used in computer networking to find ways for two computers to talk to each other **as directly as possible** in P2P networking.

Generally uses UDP under the hood.

Why do we avoid TCP for real-time communication?

- head-of-line blocking problem
- assuming packets are sent in the following order: C -> B -> A->
- if we lose packet A, we cannot process packets B and C until A is retransmitted
- so we have to wait -> latency
- codecs can deal with lost data to some degree

Head of line blocking problem

Ex. Exchange ICE candidates between Peer Connections

- When there is a new candidate on pc1, add it to pc2.
- Hint: use https://developer.mozilla.org/en-US/docs/Web/API/RTCPeerConnection/icecandidate_event
- Hint: use <https://developer.mozilla.org/en-US/docs/Web/API/RTCPeerConnection/addIceCandidate>
- Hint: use **event.candidate**

Ex. Find in <chrome://webrtc-internals>

- codecs
- packets sent per second
- bits sent per second
- qualityLimitationDurations

Hint: Look for outbound-rtp tab.

What is RTP?

What is RTP?

- UDP is a very simple protocol - it doesn't contain sequence numbers or timestamps
- We need:
 - means for detecting packet loss and reorders
 - means for synchronization and playback time
 - information about codecs
 - identifiers to map packets to tracks/SDP m-lines

RTP packet

RTP flow

RTCP - RTP Control Protocol

- Used for:
 - synchronization
 - bandwidth estimation
 - Jitter calculation

Ex. Run chrome with logs and find information about the first RTP packet

```
chromium --enable-logging='stderr' --vmodule='*/webrtc/*=2'
```

Important: close all chrome instances before running this command.

Ex. Dump RTP packets sent/received by a browser

- <https://github.com/elixir-webrtc/workshop>
- ex5

RTP tips&tricks

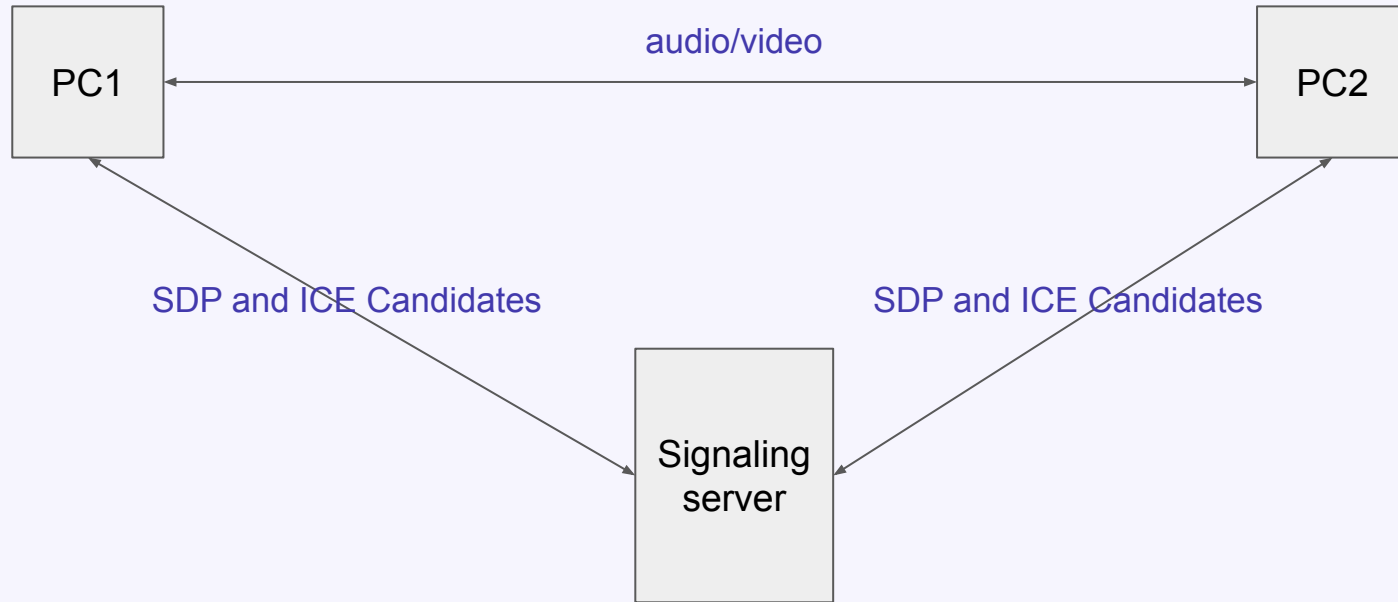

- RTP header is not encrypted
- RTP header extension carries additional information e.g. MID identifier that allows to bind RTP packet with m-line section in the SDP
- Payload type is a number identifying codec used. 96–127 is a dynamic range meaning exact meaning is conveyed in the SDP

Signaling

Signaling

Signaling

- WebSockets
- SIP
- BroadcastChannel
- this can basically be anything, from an email to even a pigeon :)

Ex. Modify the previous example to run between two tabs

- <https://github.com/elixir-webrtc/workshop/>
- ex3

Ex. Modify ex3 to establish bidirectional connection in a single negotiation

- <https://github.com/elixir-webrtc/workshop>
- ex4

Why does it work?

Ex. Inspect offer of pc1

v=0

m=audio 9 UDP/TLS/RTP/SAVPF 111 0

a=sendrecv

a=rtpmap:111 opus/48000/2

a=rtpmap:0 PCMU/8000

m=video 9 UDP/TLS/RTP/SAVPF 96 98

a=sendrecv

a=rtpmap:96 VP8/90000

a=rtpmap:98 VP9/90000

Transmitter + Receiver = Transceiver

Transceiver

- can send, receive, or send and receive tracks
- one transceiver can handle only one type of track - either audio or video
- transceiver has a direction - sendonly, recvonly, sendrecv, inactive
- <https://developer.mozilla.org/en-US/docs/Web/API/RTCRtpTransceiver>

SDP rules

- every transceiver maps to a single mline
- the number of mlines in offer and answer has to be the same
- the number of mlines cannot decrease
- some changes in the connection state require sending a new SDP offer/answer - this is known as renegotiation

Ex. Inspect transceivers in pc1

- Use <https://developer.mozilla.org/en-US/docs/Web/API/RTCPeerConnection/getTransceivers>
- Hint: you can pin **pc1** to the **window** to have an access to **pc1** in web browser's console: **window.pc1 = pc1**
- How many transceivers are there?
- What are their directions?
- What's the difference between direction and currentDirection?

Perfect Negotiation

- What if both sides want to modify the connection at the same time?
- One of the sides has to be the polite one and revert its changes.
- Use **setLocalDescription({type: “rollback”})**
- <https://developer.mozilla.org/en-US/docs/Web/API/RTCSessionDescription/ty>
[pe](#)
- <https://blog.mozilla.org/webrtc/perfect-negotiation-in-webrtc/>

WHIP/WHEP

WHIP/WHEP

- classic WebRTC doesn't standardize signaling mechanism
- there are a lot of simple scenarios that don't use renegotiation - e.g. streaming

WHIP

- a simple protocol based on HTTP for supporting WebRTC as media ingestion method
- it describes very specific usage of WebRTC
- uses HTTP for exchanging SDP offer/answer and ICE candidates
- can only send up to one audio and one video
- there is no renegotiation
- Example: OBS can use WHIP to stream media to a server

WHEP

- the same as WHEP but for egress
- web clients can use it to receive media from a server

Ex. Stream from OBS to the Broadcaster

- Open OBS and go to **Settings > Stream**.
- Change **Service** to **WHIP**.
- Pass <https://bigfish.jellyfish.ovh/api/whip> as the **Server** value and *webrtcworkshop* as the **Bearer Token**. Press **Apply**.
- Go to **Settings > Output**.
- Set **bitrate** to 500kbps. Press **Apply**.
- Choose a source of your liking (e.g. a webcam feed) and press **Start Streaming**.
- Access <https://bigfish.jellyfish.ovh>.

Mastering Transceivers

Ex. Negotiate unidirectional session without MediaStreamTracks

Follow: https://hexdocs.pm/ex_webrtc/mastering_transceivers.html#warmup

Ex. Offer to receive data

Follow: https://hexdocs.pm/ex_webRTC/mastering_transceivers.html#warmup

Ex. Negotiate bidirectional session without MediaStreamTracks

Follow:

https://hexdocs.pm/ex_webrtc/mastering_transceivers.html#bidirectional-connection-using-a-single-negotiation

Ex. Reject incoming track

Follow:

https://hexdocs.pm/ex_webrtc/mastering_transceivers.html#rejecting-incoming-track

Media Servers

Media Servers

Media Servers

Media Servers

Media Servers

Media Servers

- hide negotiation process - SDKs
- operate on higher abstraction level
- perform a lot of end to end optimizations
 - display only N video tiles
 - adaptive streaming - send different qualities (resolutions, FPS) depending on the needs - connection bandwidth, grid layout, user preferences, etc.
 - don't send video when the user switches a tab
- can provide additional features - recordings, transcriptions

Ex. Videoconferencing app using Fishjam Cloud

- <https://github.com/elixir-webrtc/workshop/>
- ex6

Thank you! :)
